Name of the Project: Vendor Comparison and Procurement Assistant

Description of the project:

The Vendor Comparison and Procurement Assistant is an n8n-based demonstration for a retail business evaluating quotations for store equipment. A procurement employee begins by entering request details in the Procurement Intake Form and uploading supplier quotation documents. Gemini analyses the submitted documents to extract and organise key details, including quoted cost, delivery period, warranty and payment terms. The uploaded quotations and procurement policy are then prepared for a consistent, criteria-based comparison.

After the quotations are scored, the workflow presents a recommended supplier to a human reviewer. The reviewer can approve the proposed vendor, choose an alternative or reject the recommendation. The final output is a simulated procurement decision; the workflow does not independently place orders or commit funds.

Problem / Opportunity Statement:

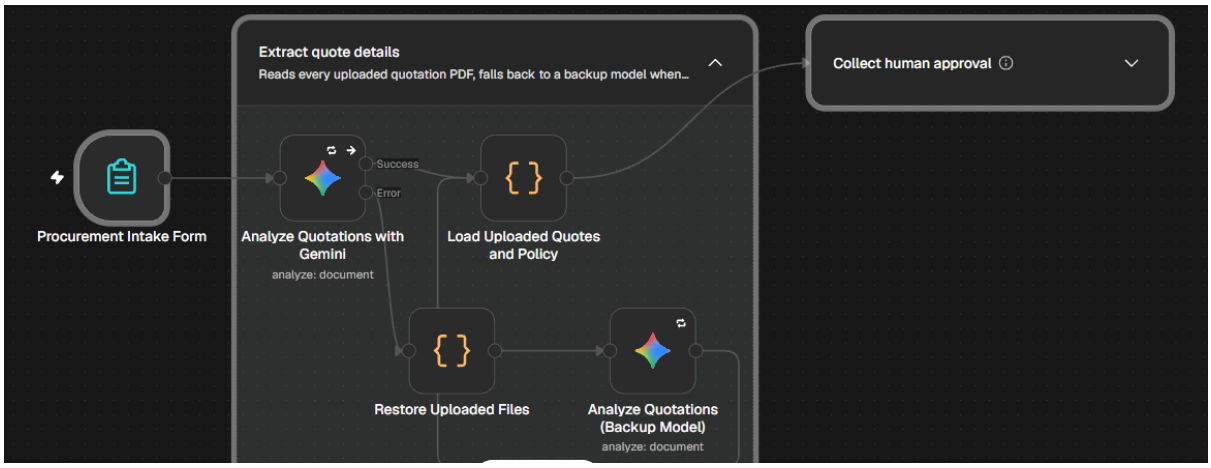

Supplier quotations often arrive as separate files with different layouts, terms and levels of detail. Comparing price alone can overlook delivery delays, warranty limitations or procurement-policy requirements. Manual transcription also increases effort and makes it harder to explain why one vendor was preferred.

This project provides a structured intake, document analysis and transparent vendor scoring process. It aims to make quotations easier to compare while retaining the procurement reviewer's authority to confirm, override or reject the recommendation.

AI Tools / Applications Used:

n8n coordinates the workflow from quotation intake to the final result. Its form nodes collect purchase-request details and the reviewer's decision. Code nodes load the uploaded quote data and procurement policy, calculate vendor scores, prepare the review and validate the final response. The visible workflow keeps extraction and approval as separate stages.

Gemini supports quotation-document analysis through the “Analyze Quotations with Gemini” node. The workflow also includes an error path that restores uploaded files and calls an “Analyze Quotations (Backup Model)” node if the primary analysis cannot complete. This design supports continuity, although any extracted information still requires verification before use.

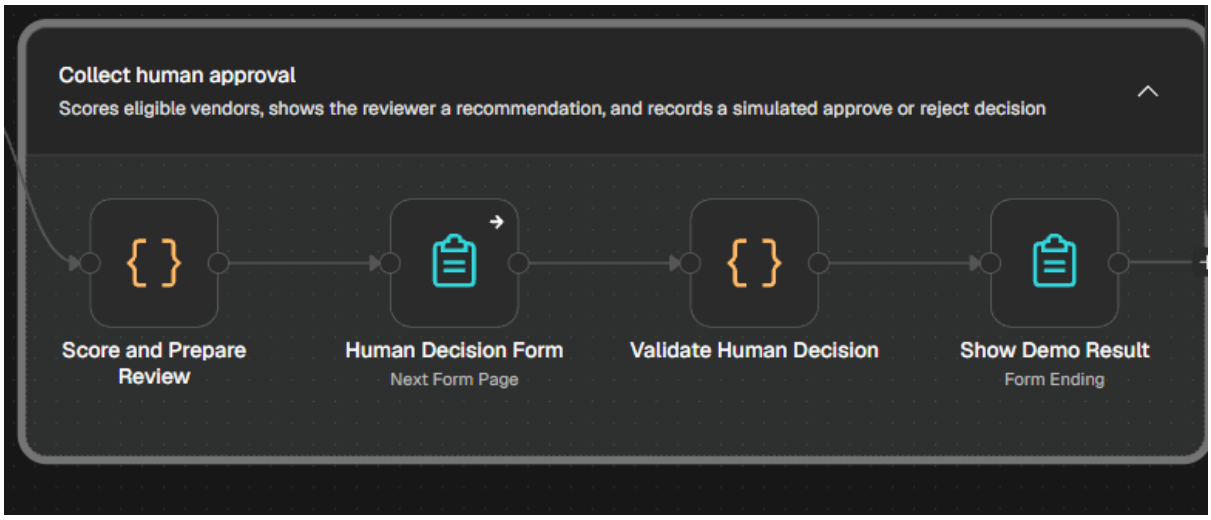

ChatGPT supports the preparation of the three fictional vendor quotations and the written project materials. PDF quotation files provide supplier inputs for the demonstration, while procurement-policy details supply rules against which offers can be reviewed. These tools assist in organising and interpreting information; they are not substitutes for checking prices, document completeness or commercial terms.

The procurement user remains the final decision-maker. In the Human Decision Form, the reviewer examines the proposed supplier and records an approval, a reasoned change of vendor or a rejection before the workflow generates the demonstration result.

Potential outcome / benefits from the project:

The assistant can reduce repetitive manual work involved in reading and comparing supplier quotations. By bringing price, delivery, warranty and payment information into a common evaluation, it helps procurement teams identify differences between offers and document the basis for a recommendation. The scoring stage encourages a repeatable approach rather than an unsupported selection based only on the lowest quotation.

The workflow also makes the decision process more reviewable. A designated procurement employee sees the recommendation in the Human Decision Form, can select a different vendor or reject the proposal, and submits the final choice for validation. The form-ending step then presents a demonstration outcome without creating an actual purchase or financial obligation.

Expected benefits include clearer vendor comparisons, improved consistency in policy checks, more visible human accountability and less time spent assembling information for a decision. The backup quotation-analysis route adds resilience if the primary AI step fails. However, the demonstration is not evidence of measured cost or time savings; these benefits would need to be tested in a real procurement setting.
